

Linear Response Theory: Two Regimes, Two Equivalent Descriptions, and Two Parts of Electrical Conductivities

Xiaodong Hu*

Department of Physics, Boston College

(Dated: August 25, 2021)

In this letter, we will review the general theory of isothermal linear response adiabatic linear response. Taking adiabatic charge current response as one example, we will show that the standard form of the conductivity tensor, consisting of paramagnetic and diamagnetic parts, can also be obtained by coupling with electrical potentials. We discuss the cancellation of diamagnetic parts at the uniform limit in metals, and derive some other useful forms of Kubo formula for future reference.

I. LINEAR RESPONSE THEORY

The problem of linear-response is formulated as following:

Consider an system in equilibrium coupling with external driven forces through a perturbative fields $F(t)$ (switching on from t_0 , for example)

$$\hat{H} = \hat{H}_0 + \hat{H}'(t) \equiv \hat{H}_0 + F(t)\hat{B}(t), \quad (1)$$

then for small fields $F(t)$, the measurable quantum average of the operator (in Schrödinger picture, for example)

$$\langle A \rangle(t) \equiv \frac{1}{\mathcal{Z}} \text{Tr}\{\hat{\rho}_S(t)\hat{A}\} \equiv \frac{1}{\mathcal{Z}} \sum_{\psi} \langle \psi_S(t) | \hat{\rho}_S(t) \hat{A} | \psi_S(t) \rangle \quad (2)$$

*Electronic address: xiaodong.hu@bc.edu

can be expand to the first order of $F(t)$, which is believed to reflect the intrinsic properties of the material. However, depending on the treatment of the perturbation in (2), or more precisely whether we are in the *fast* or *slow* limit¹, we will fall into two regimes — the (usual) *adiabatic responses* and *isothermal responses*.

A. Isothermal Response

For isothermal reponses, the perturbation is *slow* enough so that the system is always in quasi-equilibrium. So we can directly write down

$$\hat{\rho}(t) = \frac{1}{\mathcal{Z}} e^{-\beta \hat{H}} = \frac{1}{\mathcal{Z}} e^{-\beta(\hat{H}_0 + \hat{H}'(t))}. \quad (3)$$

But even the density matrix is known, it is still hard to expand to the first order of $F(t)$ and evaluate the quantum average for (2). Following [2], we can make use of the analogy of imaginary-time and inverse-temperature to define a function of β as

$$V(\beta) \equiv e^{-\beta \hat{H}} e^{\beta \hat{H}_0} = e^{-\beta(\hat{H}_0 + \hat{H}'(t))} e^{\beta \hat{H}_0}.$$

Clearly we have

$$\begin{aligned} \frac{dV(\beta)}{d\beta} &= e^{-\beta \hat{H}(t)} \hat{H}_0 e^{\beta \hat{H}_0} - e^{-\beta \hat{H}(t)} \hat{H}'(t) e^{\beta \hat{H}_0} \equiv e^{-\beta \hat{H}(t)} \hat{H}'(t) e^{\beta \hat{H}_0} \\ &\equiv e^{-\beta \hat{H}(t)} e^{\beta \hat{H}_0} \cdot e^{-\beta \hat{H}_0} \hat{H}'(t) e^{\beta \hat{H}_0} \equiv V(\beta) \hat{H}'_I(t + i\hbar\beta), \end{aligned}$$

where $\hat{H}'_I(t + i\hbar\lambda) \equiv F(t) \hat{B}(i\hbar\lambda)$. This differential equation is equivalent to the integral equation (check by differentiation)

$$V(\beta) = 1 + \int_0^\beta d\lambda V(\lambda) \hat{H}'_I(t + i\hbar\lambda), \quad (4)$$

which can be solved iteratively. To the first-order approximation, we can take $\hat{H}'(t) = 0$ in the definition of $V(\beta)$ (so to the zeroth order $V(\beta) = 1$), getting

$$V(\beta) \simeq 1 + \int_0^\beta d\lambda \hat{H}'_I(t + i\hbar\lambda) \quad (5)$$

So

$$e^{-\beta \hat{H}(t)} \equiv V(\beta) e^{-\beta \hat{H}_0} \simeq \left(1 + \int_0^\beta d\lambda \hat{H}'_I(t + i\hbar\lambda) \right) e^{-\beta \hat{H}_0} \quad (6)$$

and the variation of the quantum average of the operator \hat{A} takes the form of

$$\delta \langle \hat{A} \rangle = \frac{1}{\mathcal{Z}} \text{Tr} \{ e^{-\beta \hat{H}(t)} \hat{A} \} - \frac{1}{\mathcal{Z}} \text{Tr} \{ e^{-\beta \hat{H}_0} \hat{A} \} = \int_0^\beta d\lambda \langle \hat{A} \hat{H}'_I(t + i\hbar\lambda) \rangle_0 = \int_0^\beta d\lambda \langle \hat{A} e^{-\beta \hat{H}_0} \hat{B} e^{\beta \hat{H}_0} \rangle F(t). \quad (7)$$

The *isothermal response*

$$\chi_{AB}^T \equiv \int_0^\beta d\lambda \langle \hat{A} e^{-\lambda \hat{H}_0} \hat{B} e^{\lambda \hat{H}_0} \rangle \quad (8)$$

can be easily expressed in the energy basis: splitting into the cases when $m \neq n$ and $m = n$ and perform the integral over inverse-temperature, we have

$$\chi_{AB}^T = \sum_{m,n} \int_0^\beta d\lambda e^{-\beta \varepsilon_n} A_{nm} e^{-\lambda \varepsilon_m} B_{mn} e^{-\lambda \varepsilon_n} = \sum_{\substack{m,n \\ m \neq n}} A_{nm} B_{mn} \frac{e^{-\beta \varepsilon_m} - e^{-\beta \varepsilon_n}}{\varepsilon_n - \varepsilon_m} - \beta \sum_n e^{-\beta \varepsilon_n} A_{nn} B_{nn}. \quad (9)$$

¹ Following [1], the perturbation is fast if the density matrix can be taken as the one in old equilibrium, while is slow if the system is always in (new) quasi-equilibrium.

B. Adiabatic Response

For the more widely-used adiabatic responses, however, **we have no assumption on the form of the time-dependent density matrix, but can only determine it from the definition**

$$\dot{\hat{\rho}}_S(t) = \frac{1}{i\hbar} [\hat{H}_0 + \hat{H}'(t), \hat{\rho}_S(t)]. \quad (10)$$

Note 1. There are some literatures² going that the characteristic of the adiabatic response is that the density matrix can be assumed to stay as the same one in the old equilibrium $\hat{\rho}(t) = e^{-\beta\hat{H}_0}/\mathcal{Z}$ so that all-time dependence of adiabatic responses original from the time-evolved states. Such claim is true at least for linear response (giving the same result), but I am not sure if this is true for non-linear response as well. So I would not address in this way.

To solve the Liouville equation (10), it is helpful to switch into the interaction picture $\hat{\rho}_I(t) \equiv U_0^{-1}(t)\hat{\rho}_S(t)U_0(t) \equiv e^{\frac{i}{\hbar}\hat{H}_0 t}\hat{\rho}_S(t)e^{-\frac{i}{\hbar}\hat{H}_0 t}$, leaving

$$\dot{\hat{\rho}}_I(t) = \frac{1}{i\hbar} U_0^{-1}(t) [\hat{H}'(t), U_0(t)\hat{\rho}_I(t)U_0^{-1}(t)] U_0(t) = \frac{1}{i\hbar} [\hat{H}'_I(t), \hat{\rho}_I(t)] \equiv \hat{L}'_I \hat{\rho}_I(t), \quad (11)$$

where the interaction picture operator $\hat{H}'_I(t) \equiv U_0^{-1}(t)\hat{H}'(t)U_0(t) \equiv e^{\frac{i}{\hbar}\hat{H}_0 t}\hat{H}'(t)e^{-\frac{i}{\hbar}\hat{H}_0 t}$ and we introduce a Liouville operator $\hat{L}'_I \hat{\rho} := \frac{1}{i\hbar} [\hat{H}'_I, \hat{\rho}]$.

Differential equation (11) can be solved iteratively: the zeroth-order solution is just the old equilibrium density matrix $\hat{\rho}_I(t_0) \equiv \hat{\rho}_S(t_0) \equiv \rho_0$, the first-order solution is obtained by inserting $\hat{\rho}_0$ into (11), the second order is obtained by inserting the first-order, and so on. Namely, $\hat{\rho}_I(t)$ can be expressed in terms of *Dyson series*

$$\begin{aligned} \hat{\rho}_I(t) &= \hat{\rho}_0 + \frac{1}{i\hbar} \int_{t_0}^t d\tau \hat{L}'_I(\tau) \hat{\rho}_0 + \left(\frac{1}{i\hbar}\right)^2 \int_{t_0}^t d\tau_2 \int_{t_0}^{\tau_2} d\tau_1 \hat{L}'_I(\tau_2) \hat{L}'_I(\tau_1) \hat{\rho}_0 + \dots \\ &= \hat{\rho}_0 + \frac{1}{i\hbar} \int_{t_0}^t d\tau [\hat{H}'_I(\tau), \hat{\rho}_0] + \left(\frac{1}{i\hbar}\right)^2 \int_{t_0}^t d\tau_2 \int_{t_0}^{\tau_2} d\tau_1 [\hat{H}'_I(\tau_2), [\hat{H}'_I(\tau_1), \hat{\rho}_0]] + \dots \end{aligned} \quad (12)$$

Therefore, the evaluation of (2) can be done in the interaction picture by cycling the trace

$$\begin{aligned} \langle \hat{A} \rangle(t) &\equiv \text{Tr}\{\hat{\rho}_S(t)\hat{A}_S\} = \text{Tr}\{\hat{\rho}_I(t)e^{\frac{i}{\hbar}\hat{H}_0 t}\hat{A}_S e^{-\frac{i}{\hbar}\hat{H}_0 t}\} \equiv \text{Tr}\{\hat{\rho}_I(t)\hat{A}_I(t)\} \\ &= \text{Tr}\{\hat{\rho}_0\hat{A}_I(t)\} + \frac{1}{i\hbar} \int_{t_0}^t d\tau \text{Tr}\{[\hat{H}'_I(\tau), \hat{\rho}_0]\hat{A}_I(t)\} + \left(\frac{1}{i\hbar}\right)^2 \int_{t_0}^t d\tau_2 \int_{t_0}^{\tau_2} d\tau_1 \text{Tr}\left\{[\hat{H}'_I(\tau_2), [\hat{H}'_I(\tau_1), \hat{\rho}_0]]\hat{A}_I(t)\right\} + \dots \\ &= \langle \hat{A} \rangle_0 + \frac{1}{i\hbar} \int_{t_0}^t d\tau \langle [\hat{A}_I(t), \hat{H}'_I(\tau)] \rangle_0 + \left(\frac{1}{i\hbar}\right)^2 \int_{t_0}^t d\tau_2 \int_{t_0}^{\tau_2} d\tau_1 \langle [[\hat{A}_I(t), \hat{H}'_I(\tau_2)], \hat{H}'_I(\tau_1)] \rangle_0 + \dots, \end{aligned} \quad (13)$$

where the first term (equilibrium average) is vanishing due to Bloch's theorem, and for the other terms identity

$$\text{Tr}\{[A, B]C\} \equiv \text{Tr}\{B[C, A]\}.$$

is used to take out $\hat{\rho}_0$ and recover the quantum average. Without loss of generality, from now on we take $t_0 \rightarrow -\infty$.

If $\hat{H}'(t)$ is introduced in the way of (1), the linear response is

$$\delta\langle \hat{A} \rangle^{(1)}(t) = \frac{1}{i\hbar} \int_{-\infty}^t dt' \langle [\hat{A}_I(t), \hat{B}_I(t')] \rangle_0 \cdot F(t'), \quad (14)$$

or in terms of *retarded* Green function

$$\delta\langle \hat{A} \rangle^{(1)}(t) = \frac{1}{\hbar} \int_{-\infty}^{\infty} dt' G_{AB}^R(t, t') F(t'), \quad G_{AB}^R(t, t') = (-i)\theta(t - t') \langle [\hat{A}_I(t), \hat{B}_I(t')] \rangle_0 \quad (15)$$

² Like Sec. 3.2.1 of [3] and Sec. 8.3 of [2].

if the integral (14) is extended to the entire domain of time.

Note 2. Comparing (14) with (7), the most intuitive difference of isothermal response function and adiabatic response function is that the former one does not depend on time! This is reasonable since the time-evolution of isothermal processes cannot be perceived by the system (it is always in quasi-equilibrium).

Note that by cycling the time arguments of operator \hat{A} and \hat{B} in the retarded Green function, $G_{AB}^R(t, t') \equiv G_{AB}^R(t - t', 0)$ so the R.H.S. of (15) has exactly the form of a *convolution*. According to convolution theorem³, we have, in frequency domain,

$$\delta\langle\hat{A}\rangle(\omega) = \chi_{AB}(\omega)F(\omega), \quad (16)$$

where

$$\chi_{AB}(\omega) \equiv \mathbb{F}\left[\frac{1}{\hbar}G_{AB}^R(t, 0)\right] \equiv \lim_{s \rightarrow 0^+} \frac{1}{\hbar}G_{AB}^R(\varpi) = \lim_{s \rightarrow 0^+} \frac{1}{i\hbar} \int_0^\infty dt \langle[\hat{A}_I(t), B_I]\rangle_0 e^{i\varpi t}, \quad (17)$$

where an infinitesimal positive number is inserted $\varpi \equiv \omega + is$ because the retarded function $G_{AB}^R(\varpi)$ is analytical only on the upper-half plane of the frequency domain [4]. Another thing that needs to keep in mind is that unlike the integration domain in time space in (15), for response function in frequency space the integration is taken within $[0, +\infty)$.

Moreover, if the system remains translation-invariant (this happens at least when we concern about only long wavelength physics) $\chi_{AB}(\mathbf{r}, \mathbf{r}'; \omega) \equiv \chi_{AB}(\mathbf{r} - \mathbf{r}'; \omega)$, the response function in momentum space

$$\langle\hat{A}\rangle(\mathbf{q}, \omega) = \chi_{AB}(\mathbf{q}, \omega)F(\omega)$$

reads

$$\chi_{AB}(\mathbf{q}, \omega) = \lim_{s \rightarrow 0^+} \frac{1}{i\hbar V} \int_0^\infty dt \langle[\hat{A}_I(\mathbf{q}, t), \hat{B}_I(-\mathbf{q}, 0)]\rangle_0 e^{i\varpi t}. \quad (18)$$

This is because (taking Fourier transformation to second-quantized operators)

$$\begin{aligned} \chi_{AB}(\mathbf{r}, \mathbf{r}'; \omega) &\equiv \lim_{s \rightarrow 0^+} \frac{1}{i\hbar V} \int_0^\infty dt \sum_{\mathbf{k}, \mathbf{k}'} e^{i\mathbf{k} \cdot \mathbf{r}} e^{i\mathbf{k}' \cdot \mathbf{r}'} \langle[\hat{A}_I(\mathbf{k}, t), \hat{B}_I(\mathbf{k}', 0)]\rangle_0 e^{i\varpi t} \\ &\equiv \lim_{s \rightarrow 0^+} \frac{1}{i\hbar V} \int_0^\infty dt \sum_{\mathbf{k}, \mathbf{k}'} e^{i\mathbf{k} \cdot (\mathbf{r} - \mathbf{r}')} e^{i(\mathbf{k} + \mathbf{k}') \cdot \mathbf{r}'} \langle[\hat{A}_I(\mathbf{k}, t), \hat{B}_I(\mathbf{k}', 0)]\rangle_0 e^{i\varpi t}. \end{aligned}$$

is a function of $\mathbf{r} - \mathbf{r}'$ if and only if $\mathbf{k} + \mathbf{k}' \equiv 0$.

In the energy eigenstate, the response function takes the form of

$$\begin{aligned} \chi_{AB}(\omega) &= \lim_{s \rightarrow 0^+} \frac{1}{i\hbar} \int_0^\infty d\tau \sum_{m, n} (e^{-\beta\varepsilon_n} - e^{-\beta\varepsilon_m}) A_{nm} B_{mn} e^{\frac{i}{\hbar}(\varepsilon_n - \varepsilon_m)\tau} e^{i(\omega + is)\tau} \\ &= \lim_{s \rightarrow 0^+} \sum_{m, n} \frac{e^{-\beta\varepsilon_n} - e^{-\beta\varepsilon_m}}{\hbar\omega + \varepsilon_n - \varepsilon_m + is} A_{nm} B_{mn}. \end{aligned} \quad (19)$$

Comparing with (9), this time the denominator is always well-defined so we do not have to split into the diagonal and off-diagonal parts before performing the integral.

Note 3. The off-diagonal part of isothermal response (9) is clear to coincide with the static limit of adiabatic response $\lim_{\omega \rightarrow 0} \chi_{AB}(\omega)$, while the diagonal part of (9) is exclusive. Anyway **in general isothermal responses do not have to be the same as the static limit of adiabatic responses — they are two quite different things.**

³ The Fourier transformation of a convolution of two functions is the multiplication of each's Fourier transformation.

C. Example: Adiabatic Response of Charge Current

In this section, we will consider the electric current driven by an external electric field. In general such electric field depends on both scalar and vector potentials

$$\mathbf{E}(\mathbf{r}, t) \equiv -\nabla\phi - \frac{\partial \mathbf{A}}{\partial t}.$$

Under the minimal coupling with external vector potential, the general continuum Hamiltonian with impurity potentials V_{imp} and interacting terms U (like four-fermion Coulomb interaction)

$$H = \int d\mathbf{r} \psi^\dagger(\mathbf{r}, t) \left(-\frac{\hbar^2}{2m} \nabla^2 - \mu + V_{\text{imp}}(\mathbf{r}) \right) \psi(\mathbf{r}, t) + U \quad (20)$$

becomes (we work in SI units so $A^\mu = (\frac{\phi}{c}, \mathbf{A})$)

$$\begin{aligned} H[A_\mu] &= \int d\mathbf{r} \psi^\dagger(\mathbf{r}, t) \left(\frac{1}{2m} \left(\frac{\hbar}{i} \nabla - q\mathbf{A}(\mathbf{r}, t) \right)^2 + \frac{q}{c} \phi(\mathbf{r}, t) - \mu + V_{\text{imp}} \right) \psi(\mathbf{r}, t) + U \\ &= H[0] - \frac{q\hbar}{2im} \int d\mathbf{r} \left(\psi^\dagger(\mathbf{r}, t) \mathbf{A}(\mathbf{r}, t) \cdot \nabla \psi(\mathbf{r}, t) - \nabla \psi^\dagger(\mathbf{r}, t) \cdot \mathbf{A}(\mathbf{r}, t) \psi(\mathbf{r}, t) \right) \\ &\quad + \frac{q}{c} \int d\mathbf{r} \psi^\dagger(\mathbf{r}, t) \phi(\mathbf{r}, t) \psi(\mathbf{r}, t) + \frac{q^2}{2m} \int d\mathbf{r} \psi^\dagger(\mathbf{r}) \mathbf{A}(\mathbf{r}, t)^2 \psi(\mathbf{r}). \end{aligned} \quad (21)$$

By definition of charge current $J_\mu \equiv \frac{\delta S[A_\mu]}{\delta A_\mu}$, we get, in the metric $ds^2 = -c^2 dt^2 + d\mathbf{x}^2$

$$H[A_\mu] = H[0] - \mathbf{J} \cdot \mathbf{A} + A_0 J^0, \quad (22)$$

where

$$J^0(\mathbf{r}, t) \equiv \frac{\delta H[A_\mu]}{\delta A_0} = \frac{\delta H}{\delta(\phi/c)} = q\psi^\dagger(\mathbf{r}, t)\psi(\mathbf{r}, t), \quad (23)$$

$$J^i(\mathbf{r}, t) \equiv -\frac{\delta H[A_\mu]}{\delta A_i} = \frac{q\hbar}{2im} \left(\psi^\dagger(\mathbf{r}, t) (\partial^i \psi(\mathbf{r}, t)) - (\partial^i \psi^\dagger(\mathbf{r}, t)) \psi(\mathbf{r}, t) \right) - \frac{q^2}{m} \psi^\dagger(\mathbf{r}, t) A^i(\mathbf{r}, t) \psi(\mathbf{r}, t) =: J^{P,i}(\mathbf{r}, t) + J^{D,i}(\mathbf{r}, t), \quad (24)$$

where we introduce the *paramagnetic* part \mathbf{J}^P (of order $\mathcal{O}((A_\mu)^0)$) and *diamagnetic* part \mathbf{J}^D (of order $\mathcal{O}(A_\mu)$) of the charge current.

Keeping track of merely *linear* coupling of the Hamiltonian, i.e., separating the contribution of paramagnetic and diamagnetic parts in consideration of adiabatic linear response, we can make use of the general result of adiabatic linear response to write down the quantum average of total current at time t as

$$\begin{aligned} \langle J_\alpha(\mathbf{r}, t) \rangle^{(1)} &= \langle J_\alpha^P(\mathbf{r}, t) \rangle^{(1)} - \frac{q^2}{m} \langle \psi^\dagger(\mathbf{r}, t) \psi(\mathbf{r}, t) \rangle^{(0)} A_\alpha(\mathbf{r}, t) (1 - \delta_{\alpha 0}) \\ &= \frac{-1}{i\hbar} \int_{-\infty}^0 dt' \int d\mathbf{r}' \langle [J_{\alpha,I}^P(\mathbf{r}, t), J_{\beta,I}^P(\mathbf{r}', t')] \rangle_0 A_\beta(\mathbf{r}', t) - \frac{q^2}{m} n_0 (1 - \delta_{\alpha 0}) A_\alpha(\mathbf{r}, t) \\ &= \int d\mathbf{r}' \int dt' \left\{ \frac{-1}{i\hbar} \theta(t - t') \langle [J_{\alpha,I}^P(\mathbf{r}, t), J_{\beta,I}^P(\mathbf{r}', t')] \rangle_0 - \frac{q^2}{m} n_0 \delta_{\alpha\beta} (1 - \delta_{\alpha 0}) \delta(\mathbf{r} - \mathbf{r}') \delta(t - t') + \right\} A^\beta(\mathbf{r}', t'), \end{aligned} \quad (25)$$

where in the first line we take the zeroth-order approximation for the diamagnetic part so that the particle density remains to be spacetime-independent $n(\mathbf{r}, t) \equiv \langle \psi^\dagger(\mathbf{r}, t) \psi(\mathbf{r}, t) \rangle = n_0$ as the one in the old equilibrium (note that spacetime-fluctuation is all brought by the external stimulus). The extra minus sign for the adiabatic response of paramagnetic currents in the second line comes from the negative coupling with external vector potential (see (22)).

Since the expression in the curly brace in (25) is still a function of $t - t'$, then convolution theorem tells

$$\langle J_\alpha(\mathbf{r}, \omega) \rangle^{(1)} = \int d\mathbf{r}' \sigma_{\alpha\beta}(\mathbf{r}, \mathbf{r}'; \omega) E_\beta(\mathbf{r}', \omega), \quad (26)$$

with the conductivity matrix

$$\sigma_{\alpha\beta}(\mathbf{r}, \mathbf{r}'; \omega) = \frac{-1}{i\omega} \left[\chi_{\alpha\beta}^P + \frac{q^2}{m} n_0 \delta_{\alpha\beta} (1 - \delta_{\alpha 0}) \delta(\mathbf{r} - \mathbf{r}') \right], \quad \chi_{\alpha\beta}^P \equiv \lim_{s \rightarrow 0^+} \frac{1}{i\hbar} \int_0^\infty dt \langle [J_{\alpha,I}^P(\mathbf{r}, t), J_{\beta,I}^P(\mathbf{r}', 0)] \rangle_0 e^{i\omega t}, \quad (27)$$

where we take the gauge $\phi = 0$ and express the electric field in terms of the vector potential $\mathbf{E}(\omega) = i\omega \mathbf{A}(\omega)$ in the frequency domain. Such step of gauge fixing can be done at the very beginning to simplify the form of the current operator (by setting $J^0 = 0$).

Anyway, if the material is furthermore homogeneous $\sigma_{\alpha\beta}(\mathbf{r}, \mathbf{r}'; \omega) \equiv \sigma_{\alpha\beta}(\mathbf{r} - \mathbf{r}'; \omega)$, we have

$$\langle J_\alpha(\mathbf{q}, \omega) \rangle^{(1)} = \frac{-1}{i\omega} \left\{ \chi_{\alpha\beta}^P(\mathbf{q}, \omega) + \frac{q^2}{m} n_0 \delta_{\alpha\beta} (1 - \delta_{\alpha 0}) \right\} E^\beta(\mathbf{q}, \omega), \quad (28)$$

with the paramagnetic response function

$$\chi_{\alpha\beta}^P(\mathbf{q}, \omega) \equiv \lim_{s \rightarrow 0^+} \frac{1}{i\hbar V} \int_0^\infty dt \langle [J_{\alpha,I}^P(\mathbf{q}, t), J_{\beta,I}^P(-\mathbf{q}, 0)] \rangle_0 e^{i\omega t}. \quad (29)$$

D. Drude Formula: Cancellation of Static Diamagnetic Response in Metals

DC limit (*slow limit*) of conductivity is taken in the order of

$$\sigma_{\alpha\beta}^{\text{DC}} := \lim_{\omega \rightarrow 0} \lim_{\mathbf{q} \rightarrow 0} \sigma_{\alpha\beta}(\mathbf{q}, \omega). \quad (30)$$

A first glance of (28) tells that there is a divergence provided $\chi_{\alpha\beta}(\mathbf{q}, \omega)$ was analytic, conflicting with the physical observations for large amounts of materials. However, we will show below that for band metals (where only intra-band processes dominate) such divergence is exactly cancelled by the term containing in the paramagnetic part. Denoting $I_{\alpha\beta}(t) \equiv \langle \hat{J}_\alpha(t) \hat{J}_\beta \rangle_0$ and expressing the many-body current operator as a summation of single-particle current operator $\hat{J}_\alpha = \sum_{\mu\nu} \langle \mu | J_\alpha^{(1)} | \nu \rangle \hat{a}_\mu^\dagger \hat{a}_\nu$, we have (only *connected* diagram contributes⁴)

$$\begin{aligned} I_{\alpha\beta}(t) - I_{\beta\alpha}(t) &= \sum_{1,2,3,4} \left\langle \langle 1 | J_\alpha^{(1)} | 2 \rangle a_1^\dagger(t) a_2(t) \langle 3 | J_\beta^{(1)} | 4 \rangle a_3^\dagger a_4 \right\rangle - (\alpha \leftrightarrow \beta) \\ &= \sum_{1,2,3,4} \langle 1 | J_\alpha^{(1)} | 2 \rangle \langle 3 | J_\beta^{(1)} | 4 \rangle \left\langle 4 \left| \frac{e^{\frac{i}{\hbar} h t}}{1 + e^{\beta h}} \right| 1 \right\rangle \left\langle 2 \left| \frac{e^{-\frac{i}{\hbar} h t}}{1 + e^{-\beta h}} \right| 3 \right\rangle - (\alpha \leftrightarrow \beta) \\ &= \sum_{m,n} e^{\frac{i}{\hbar} (\varepsilon_m - \varepsilon_n) t} \langle m | J_\alpha^{(1)} | n \rangle \langle n | J_\beta^{(1)} | m \rangle \left[\frac{1}{1 + e^{\beta \varepsilon_m}} \frac{e^{\beta \varepsilon_n}}{1 + e^{\beta \varepsilon_n}} - \frac{e^{\beta \varepsilon_m}}{1 + e^{\beta \varepsilon_m}} \frac{1}{1 + e^{\beta \varepsilon_n}} \right] \\ &= \sum_{m,n} e^{\frac{i}{\hbar} (\varepsilon_m - \varepsilon_n) t} \langle m | J_\alpha^{(1)} | n \rangle \langle n | J_\beta^{(1)} | m \rangle (f_m - f_n), \end{aligned}$$

where in the second line we use, for free fermion $\hat{H}_0 = \sum_{\alpha\beta} c_\alpha^\dagger h_{\alpha\beta} c_\beta$,

$$\begin{aligned} \langle c_\alpha^\dagger(t) c_\beta \rangle &\equiv \left\langle e^{-\frac{i}{\hbar} \hat{H}_0 t} c_\alpha^\dagger e^{\frac{i}{\hbar} \hat{H}_0 t} c_\beta \right\rangle = \left\langle \left(c_\alpha^\dagger - i \frac{t}{\hbar} [\hat{H}_0, c_\alpha^\dagger] + \frac{t^2}{(2\hbar)!} [\hat{H}_0, [\hat{H}_0, c_\alpha^\dagger]] + \dots \right) c_\beta \right\rangle \\ &= \sum_\gamma \left(e^{\frac{i}{\hbar} h t} \right)_{\gamma\alpha} \langle c_\gamma^\dagger c_\beta \rangle = \left\langle \beta \left| \frac{e^{\frac{i}{\hbar} h t}}{1 + e^{\beta h}} \right| \alpha \right\rangle, \end{aligned}$$

and similarly

$$\langle c_\alpha(t) c_\beta^\dagger \rangle = \sum_\gamma \left(e^{-\frac{i}{\hbar} h t} \right)_{\alpha\gamma} \langle c_\gamma c_\beta^\dagger \rangle = \left\langle \alpha \left| \frac{e^{-\frac{i}{\hbar} h t}}{1 + e^{\beta h}} \right| \beta \right\rangle,$$

⁴ This fact is much clearer in path-integral formalism, see, for example, [5].

with h the first-quantized (single-particle) Hamiltonian. Thus by integrating out the time, the paramagnetic current-current response function reads

$$\chi_{\alpha\beta}^P(\mathbf{q}, \omega) = \lim_{s \rightarrow 0^+} \frac{1}{i\hbar V} \int_0^\infty dt (I_{\alpha\beta}(t) - I_{\beta\alpha}(t)) e^{i\omega t} = \lim_{s \rightarrow 0^+} \frac{1}{V} \sum_{m,n} (f_m - f_n) \frac{\langle m | J_\alpha^{(1)}(\mathbf{q}) | n \rangle \langle n | J_\beta^{(1)}(-\mathbf{q}) | m \rangle}{\hbar\omega + \varepsilon_m - \varepsilon_n}. \quad (31)$$

Re-expression the second-quantized paramagnetic current operator (24) as

$$J_\alpha^P = \sum_{\mathbf{r}, \mathbf{r}'} \psi(\mathbf{r})^\dagger \frac{q}{2m} \left(\langle \mathbf{r} | (-i\hbar \nabla') \mathbf{r}' \rangle + \langle (-i\hbar \nabla) \mathbf{r} | \mathbf{r}' \rangle \right) \psi(\mathbf{r}'),$$

we can immediately write down the single-particle current operator $\hat{J}_\alpha = \sum_{\mu\nu} \langle \mu | J_\alpha^{(1)} | \nu \rangle \psi_\mu^\dagger \psi_\nu$ for the i -th particle under the coordinate representation

$$J_\alpha^{(1)}(\mathbf{r}) = \frac{q}{2m} (\hat{p}_{i,\alpha} \delta(\mathbf{r} - \hat{\mathbf{r}}_i) + \delta(\mathbf{r} - \hat{\mathbf{r}}_i) \hat{p}_{i,\alpha}), \quad (32)$$

or in momentum representation

$$J_\alpha^{(1)}(\mathbf{q}) = \frac{q}{2m} (\hat{p}_{i,\alpha} e^{-\frac{i}{\hbar} \mathbf{q} \cdot \hat{\mathbf{r}}_i} + e^{-\frac{i}{\hbar} \mathbf{q} \cdot \hat{\mathbf{r}}_i} \hat{p}_{i,\alpha}). \quad (33)$$

Separating the denominator (31) into two parts, we get

$$\chi_{\alpha\beta}^P(\mathbf{q}, \omega) = \lim_{s \rightarrow 0^+} \frac{1}{V} \sum_{m,n} (f_m - f_n) \frac{\langle m | J_\alpha^{(1)}(\mathbf{q}) | n \rangle \langle n | J_\beta^{(1)}(-\mathbf{q}) | m \rangle}{\hbar\omega + \varepsilon_{mn}} \quad (34)$$

$$\equiv \lim_{s \rightarrow 0^+} \frac{1}{V} \sum_{m,n} (f_m - f_n) \langle m | J_\alpha^{(1)}(\mathbf{q}) | n \rangle \langle n | J_\beta^{(1)}(-\mathbf{q}) | m \rangle \left[\frac{1}{\varepsilon_{mn}} \left(1 - \frac{\hbar\omega}{\hbar\omega + \varepsilon_{mn}} \right) \right]. \quad (35)$$

It is clear that with the help of *f-sum rule* (the proof is given in the appendix)

$$\sum_{m,n} (f_m - f_n) \frac{\langle m | J_\alpha^{(1)}(\mathbf{q}) | n \rangle \langle n | J_\alpha^{(1)}(-\mathbf{q}) | m \rangle}{\varepsilon_m - \varepsilon_n} = -\frac{Nq^2}{m} \delta_{\alpha\beta}, \quad (36)$$

the first part of response function

$$\chi_{\alpha\beta}^{P,1st}(\mathbf{q}, \omega) \equiv \lim_{s \rightarrow 0^+} \frac{1}{V} \sum_{m,n} (f_m - f_n) \frac{\langle m | J_\alpha^{(1)}(\mathbf{q}) | n \rangle \langle n | J_\beta^{(1)}(-\mathbf{q}) | m \rangle}{\varepsilon_m - \varepsilon_n} = -\frac{q^2 n}{m} \delta_{\alpha\beta} \quad (37)$$

cancel exactly with the the diamagnetic part in the conductivity tensor (27), leaving only

$$\sigma_{\alpha\beta}(\mathbf{q}, \omega) = \frac{-1}{i\omega} \chi_{\alpha\beta}^{P,2nd} = \lim_{s \rightarrow 0^+} \frac{\hbar}{iV} \sum_{m,n} (f_m - f_n) \frac{\langle m | J_\alpha^{(1)}(\mathbf{q}) | n \rangle \langle n | J_\beta^{(1)}(-\mathbf{q}) | m \rangle}{\varepsilon_{mn}(\hbar\omega + \varepsilon_{mn})}. \quad (38)$$

Note 4. Although the motivation to think about the diamagnetic cancellation starts from taking the static limit $\omega \rightarrow 0$ of physical responses, formally the above cancellation is true for the whole energy scale!

The left task is to evaluate the quantum average within the Bloch states $|n\mathbf{k}\rangle$. For **the uniform limit $\mathbf{q} \rightarrow \mathbf{0}$ of band metals where intra-band processes dominate**, we get (spin degeneracy included)

$$\sigma_{\alpha\beta}^{\text{intra}}(\mathbf{q}, \omega) = \lim_{s \rightarrow 0^+} \frac{\hbar q^2}{i4m^2 V} \sum_{n,s} \sum_{\mathbf{k}, \mathbf{k}'} (f_{n\mathbf{k}} - f_{n\mathbf{k}'}) \frac{\langle n\mathbf{k} | \hat{p}_\alpha e^{-\frac{i}{\hbar} \mathbf{q} \cdot \hat{\mathbf{r}}} + e^{-\frac{i}{\hbar} \mathbf{q} \cdot \hat{\mathbf{r}}} \hat{p}_\alpha | n\mathbf{k}' \rangle \langle n\mathbf{k}' | \hat{p}_\beta e^{\frac{i}{\hbar} \mathbf{q} \cdot \hat{\mathbf{r}}} + e^{\frac{i}{\hbar} \mathbf{q} \cdot \hat{\mathbf{r}}} \hat{p}_\beta | n\mathbf{k} \rangle}{(\varepsilon_{n\mathbf{k}} - \varepsilon_{n\mathbf{k}'})(\hbar\omega + is + \varepsilon_{n\mathbf{k}} - \varepsilon_{n\mathbf{k}'})}.$$

Using the definition of Bloch states $\langle \mathbf{r} | n\mathbf{k} \rangle \equiv e^{i\mathbf{k} \cdot \mathbf{r}} u_n(\mathbf{r})$, we have

$$e^{\frac{i}{\hbar} \mathbf{q} \cdot \hat{\mathbf{r}}} |n\mathbf{k}\rangle = \int d\mathbf{r} e^{\frac{i}{\hbar} \mathbf{q} \cdot \hat{\mathbf{r}}} |\mathbf{r}\rangle \langle \mathbf{r} | n\mathbf{k} \rangle \equiv \int d\mathbf{r} e^{\frac{i}{\hbar} \mathbf{q} \cdot \mathbf{r}} e^{\frac{i}{\hbar} \mathbf{k} \cdot \mathbf{r}} u_n(\mathbf{r}) = |n, \mathbf{k} + \mathbf{q}\rangle,$$

and, for example $\langle n\mathbf{k}|\hat{p}_\alpha e^{-\frac{i}{\hbar}\mathbf{q}\cdot\hat{\mathbf{r}}}|n\mathbf{k}'\rangle = m\delta_{\mathbf{k},\mathbf{k}'-\mathbf{q}}\langle n\mathbf{k}|\hat{v}_\alpha|n\mathbf{k}\rangle$. Thus the intra-band conductivity

$$\sigma_{\alpha\beta}^{\text{intra}}(\mathbf{q}, \omega) = \lim_{s \rightarrow 0^+} \frac{2\hbar q^2}{iV} \sum_{n,\mathbf{k}} \frac{f_{n,\mathbf{k}} - f_{n,\mathbf{k}+\mathbf{q}}}{\varepsilon_{n,\mathbf{k}} - \varepsilon_{n,\mathbf{k}'+\mathbf{q}}} \frac{\langle n\mathbf{k}|\hat{v}_\alpha|n\mathbf{k}\rangle \langle n\mathbf{k}|\hat{v}_\beta|n\mathbf{k}\rangle}{\hbar\omega + is + \varepsilon_{n,\mathbf{k}} - \varepsilon_{n,\mathbf{k}+\mathbf{q}}}. \quad (39)$$

For quadratic dispersion relation, we have, in the uniform limit,

$$\sigma_{\alpha\beta}^{\text{intra}}(\mathbf{q} \rightarrow \mathbf{0}, \omega) \simeq \lim_{s \rightarrow 0^+} \frac{2\hbar q^2}{iV} \sum_{n,\mathbf{k}} \left(\frac{\partial f_{n\mathbf{k}}}{\partial \varepsilon_{n\mathbf{k}}} \right) \frac{\langle n\mathbf{k}|\hat{v}_\alpha|n\mathbf{k}\rangle \langle n\mathbf{k}|\hat{v}_\beta|n\mathbf{k}\rangle}{\hbar\omega + is - \frac{\hbar^2}{m}\mathbf{k} \cdot \mathbf{q}}. \quad (40)$$

Equation (40) agrees with the result derived from the Boltzmann equation (if we identify the relaxation time $\tau \sim \hbar/s$). If we further ignore the linear- \mathbf{q} term in (40), we get ($\eta \equiv s/\hbar \ll 1$)

$$\sigma_{\alpha\beta}^{\text{intra}}(\mathbf{q} \rightarrow \mathbf{0}, \omega) \simeq \lim_{\eta \rightarrow 0^+} \frac{i}{\omega + i\eta} \times \frac{2q^2}{V} \sum_{n,\mathbf{k}} \left(-\frac{\partial f_{n\mathbf{k}}}{\partial \varepsilon_{n\mathbf{k}}} \right) \langle n\mathbf{k}|\hat{v}_\alpha|n\mathbf{k}\rangle \langle n\mathbf{k}|\hat{v}_\beta|n\mathbf{k}\rangle \equiv \lim_{\eta \rightarrow 0^+} \frac{i}{\omega + i\eta} \mathcal{D}_{\alpha\beta}, \quad (41)$$

where $\mathcal{D}_{\alpha\beta}$ is the *Drude weight*. Clearly the real part of the uniform limit of the conductivity tensor takes the form of Dirac delta function

$$\text{Re } \sigma_{\alpha\beta}^{\text{intra}}(\mathbf{q} \rightarrow \mathbf{0}, \omega) = \lim_{\eta \rightarrow 0^+} \frac{1}{\pi} \frac{\eta}{\omega^2 + \eta^2} \times \pi \mathcal{D}_{\alpha\beta} = \delta(\omega) \pi \mathcal{D}. \quad (42)$$

In modern transport theory, we *define* the Drude weight as

Definition 1. (Drude-Weight)

$$\mathcal{D}_{\alpha\beta} := \lim_{\omega \rightarrow 0} \omega \text{Im } \sigma_{\alpha\beta}(\omega). \quad (43)$$

Conversely, for (perfectly diamagnetic) superconductors, it is the paramagnetic part that vanishes in the DC limit, keeping the imaginary divergent diamagnetic part. The detailed calculation of BCS superconductors can be found in Patrick Lee's lecture notes https://ocw.mit.edu/courses/physics/8-512-theory-of-solids-ii-spring-2009/lecture-notes/MIT8_512s09_lec09.pdf.

II. OTHER EQUIVALENT FORMS OF KUBO FORMULA

A. Kubo's Identities and Canonical Kubo Pair

In Kubo's original paper [6], he proved an identity:

Claim 1. (Kubo's First Identity) For any time-dependent operator (in interaction picture, for instance (for future use)) $\hat{X}_I(t) \equiv e^{\frac{i}{\hbar}\hat{H}_0(t-t_0)} \hat{X}_S(t_0) e^{-\frac{i}{\hbar}\hat{H}_0(t-t_0)}$ and density matrix $\hat{\rho}_0 = e^{-\beta\hat{H}_0}/\mathcal{Z}$, we have

$$\frac{1}{i\hbar} [\hat{X}_I(t), \hat{\rho}_0] \equiv -\hat{\rho}_0 \int_0^\beta d\lambda \dot{\hat{X}}_I(t - i\lambda\hbar), \quad \text{where} \quad \dot{\hat{X}}_I(t) \equiv \frac{1}{i\hbar} [\hat{X}_I(t), \hat{H}_0] \quad (44)$$

▷ Proving by direct check:

$$\begin{aligned} \text{RHS} &= -\hat{\rho}_0 \int_0^\beta d\lambda \frac{1}{i\hbar} [\hat{X}_I(t - i\lambda\hbar), \hat{H}_0] = -\frac{1}{i\hbar} \hat{\rho}_0 \int_0^\beta d\lambda \left[e^{\lambda\hat{H}_0} \hat{X}_I(t) e^{-\lambda\hat{H}_0}, \hat{H}_0 \right] = -\frac{1}{i\hbar} \hat{\rho}_0 \int_0^\beta d\lambda e^{\lambda\hat{H}_0} [\hat{X}_I(t), \hat{H}_0] e^{-\lambda\hat{H}_0} \\ &\equiv \frac{1}{i\hbar} \hat{\rho}_0 \int_0^\beta d\lambda \frac{d}{d\lambda} \left[e^{\lambda\hat{H}_0} \hat{X}_I(t) e^{-\lambda\hat{H}_0} \right] = \frac{1}{i\hbar} \left(\hat{\rho}_0 e^{\beta\hat{H}_0} \hat{X}_I(t) e^{-\beta\hat{H}_0} - \hat{\rho}_0 \hat{X}_I(t) \right) = \frac{1}{i\hbar} [\hat{X}_I(t), \hat{\rho}_0]. \end{aligned}$$

□

If we introduce the *canonical Kubo pair* [7] (still for operators in interaction picture, for instance (for future use))

$$\langle\langle A; B \rangle\rangle := \frac{1}{\beta} \int_0^\beta d\lambda \langle A_I(-i\hbar\lambda) B_I(0) \rangle_0. \quad (45)$$

then a neat form of *Kubo's second identity* can be immediately obtained

Corollary 1. (Kubo's Second Identity)

$$\beta \langle \langle [H_0, B]; A(t) \rangle \rangle \equiv \langle [A_I(t), B_I(0)] \rangle_0. \quad (46)$$

▷ By Kubo's first identity (44), we have

$$\begin{aligned} \text{LHS} &= i\hbar \int_0^\beta d\lambda \langle -\dot{B}_I(-i\lambda\hbar) \hat{A}_I(t) \rangle = \text{Tr} \left\{ i\hbar \left(-\hat{\rho} \int_0^\beta d\lambda \dot{B}_I(-i\lambda\hbar) \right) \hat{A}_I \right\} \\ &= \text{Tr} \{ [\hat{B}(0), \hat{\rho}_0] \hat{A}_I(t) \} = \text{Tr} \{ \hat{\rho}_0 [\hat{A}_I(t), \hat{B}_I(0)] \} = \text{RHS}. \end{aligned}$$

□

B. Equivalent Forms of Kubo Formula

There are many forms of Kubo formula used in literatures. In this section, we will try to derive all of them.

Applying Kubo's second identity to the general adiabatic response in frequency domain (17), the response function can be re-written as

$$\begin{aligned} \chi_{AB}(\omega) &= \lim_{s \rightarrow 0^+} \frac{1}{i\hbar} \int_0^{+\infty} dt \langle [\hat{A}_I(t), \hat{B}_I(0)] \rangle_0 e^{i\omega t} = \lim_{s \rightarrow 0^+} \frac{\beta}{i\hbar} \int_0^{+\infty} dt \langle \langle [H_0, B]; A(t) \rangle \rangle e^{i\omega t} \\ &\equiv \lim_{s \rightarrow 0^+} \frac{\beta}{i\hbar} \int_0^{+\infty} dt e^{i\omega t} \int_0^\beta d\lambda \langle [H_0, B_I(-i\hbar\lambda)] A_I(t) \rangle. \end{aligned} \quad (47)$$

Particularly, for charge current response, if external sources is introduced in the way of Luttinger [1], i.e., $H_0 \mapsto H = H_0 + Q(\varphi, t)e^{i\omega t}$, or $\hat{B}(\mathbf{r}, t) \equiv Q(\varphi, t)$ and $F(t) = e^{i\omega t}$, we have, the current response (in the language of [8])

$$\langle J(\delta\gamma) \rangle(\omega) = \sigma_{\gamma\varphi}(\omega) \cdot e^{i\omega t}$$

with

$$\begin{aligned} \sigma_{\gamma\varphi}(\omega) &= \lim_{s \rightarrow 0^+} \frac{\beta}{i\hbar} \int_0^{+\infty} dt \langle \langle [H_0, Q(\varphi)]; J(\delta\gamma, t) \rangle \rangle e^{i\omega t} \\ &= \lim_{s \rightarrow 0^+} \beta \int_0^{+\infty} dt \langle \langle J(\delta\varphi); J(\delta\gamma, t) \rangle \rangle e^{i\omega t} \equiv \lim_{s \rightarrow 0^+} \beta \int_0^{+\infty} dt \langle \langle J(\delta\gamma, t); J(\delta\varphi) \rangle \rangle e^{i\omega t}, \end{aligned} \quad (48)$$

where charge conservation law

$$\frac{dQ(\varphi)}{dt} = -(\partial J)(\varphi) \equiv -J(\delta\varphi) \quad (49)$$

and symmetric properties of Kubo canonical pairs $\langle \langle A; B \rangle \rangle \equiv \langle \langle B; A \rangle \rangle$ are used. Equation (48) is used in [8] for static response $\omega = 0$.

Note 1. One must be aware that here **the notation $J(\delta\gamma)$ indicates the *total* current that satisfies the charge conservation law.** We do NOT explicitly separate the current operator into paramagnetic and diamagnetic part as we have done in the former formulation.

Note 2. In fact, relation (48), and its descendents of thermoelectrical and thermal transports,

$$\alpha_{\gamma\psi}(\omega) = \lim_{s \rightarrow 0^+} \beta^2 \int_0^{+\infty} dt \langle \langle J(\delta\gamma, t); J^E(\delta\psi) \rangle \rangle e^{i\omega t}, \quad (50)$$

$$\kappa_{\gamma\psi}(\omega) = \lim_{s \rightarrow 0^+} \beta^2 \int_0^{+\infty} dt \langle \langle J^E(\delta\gamma, t); J^E(\delta\psi) \rangle \rangle e^{i\omega t}, \quad (51)$$

are quite general since they are derived from basic operation at the operator-level. Below we will show that equation (48) will go back to the familiar form (27) if is applied to a system of *parabolic* dispersion.

C. Equivalence between Conductivity Obtained by Coupling with Vector Potentials and Electrical Potentials

Electrical conductivities are separated by paramagnetic part and diamagnetic part as we have shown before. They are derived by coupling the system to external vector potentials (with the gauge choice $\varphi = 0$). Is such prescription the same as that proposed by Luttinger? In this section, we will answer this question in two approaches.

1. Approach 1

The first approach starts from the original form of (47) without employing the Kubo's second identity (which is also a general formula). Namely,

$$\sigma_{\gamma\varphi}(\omega) = \lim_{s \rightarrow 0^+} \frac{1}{i\hbar} \int_0^\infty dt \langle [J(\delta\gamma, t), Q(\varphi, 0)] \rangle_0 e^{i\omega t}. \quad (52)$$

Integration by parts, and making use of the charge conservation law (49), we get

$$\begin{aligned} \sigma_{\gamma\varphi}(\omega) &\equiv \lim_{s \rightarrow 0^+} \frac{1}{i\hbar} \int_0^\infty dt \langle [J(\delta\gamma, 0), Q(\varphi, -t)] \rangle e^{i\omega t} \\ &\equiv \lim_{s \rightarrow 0^+} \frac{1}{i\omega} \frac{1}{i\hbar} \left\{ -\langle [J(\delta\gamma, 0), Q(\varphi, 0)] \rangle - \int_0^\infty dt \langle [J(\delta\gamma, 0), J(\delta\varphi, -t)] \rangle e^{i\omega t} \right\} \\ &\equiv \lim_{s \rightarrow 0^+} \frac{i}{\omega + is} \times \left\{ \frac{1}{i\hbar} \langle [J(\delta\gamma, 0), Q(\varphi, 0)] \rangle + \frac{1}{i\hbar} \int_0^\infty dt \langle [J(\delta\gamma, t), J(\delta\varphi, 0)] \rangle e^{i\omega t} \right\}. \end{aligned} \quad (53)$$

Comparing with (41), we recognize the Drude weight

$$\mathcal{D}_{\gamma\varphi} = \lim_{s \rightarrow 0^+} \frac{1}{V} \left\{ \frac{1}{i\hbar} \langle [J(\delta\gamma, 0), Q(\varphi, 0)] \rangle + \frac{1}{i\hbar} \int_0^\infty dt \langle [J(\delta\gamma, t), J(\delta\varphi, 0)] \rangle e^{i\omega t} \right\}. \quad (54)$$

The second part of (53) or (54),

$$\Sigma_{\gamma\varphi}(\omega) := \frac{1}{i\hbar} \int_0^\infty dt \langle [J(\delta\gamma, t), J(\delta\varphi, 0)] \rangle e^{i\omega t}, \quad (55)$$

may remind you of the response function of the *paramagnetic* current (29), but they are DIFFERENT — In the formulation of Luttinger, all current operators in consideration are the *total* current. But if you do want to go back to the vector potential formulation with *parabolic* dispersion relation, up to linear response (so that there should be NO dependence of A_μ in the conductivity) $\Sigma_{\gamma\varphi}(\omega)$ will degenerate correctly to the paramagnetic response function

$$\Sigma_{\gamma\varphi}(\omega) \rightarrow \chi_{\gamma\varphi}(\omega) + \mathcal{O}(A_\mu)$$

since $J(\delta\gamma) = J^P(\delta\gamma) + J^D(\delta\gamma)$ and $J^D(\delta\gamma) \propto A_\gamma$.

To show the result (54) matches exactly with (28) to the systems with parabolic dispersion up to linear response, the left task is to prove that the first term of (54) is nothing but the diamagnetic part of contribution. In fact,

$$\begin{aligned} \frac{1}{i\hbar} \langle [J(\delta\gamma), Q(\varphi)] \rangle_0 &= \frac{1}{i\hbar V} \sum_{1,2,3,4} \left\langle \langle 1 | J^{(1)}(\delta\gamma) | 2 \rangle a_1^\dagger a_2 \langle 3 | Q^{(1)}(\varphi) | 4 \rangle a_3^\dagger a_4 \right\rangle - \left\langle \langle 3 | Q^{(1)}(\varphi) | 4 \rangle a_3^\dagger a_4 \langle 1 | J^{(1)}(\delta\gamma) | 2 \rangle a_1^\dagger a_2 \right\rangle \\ &= \frac{1}{i\hbar} \sum_{m,n} \langle m | J^{(1)}(\delta\gamma) | n \rangle \langle n | Q^{(1)}(\varphi) | m \rangle (f_m(1 - f_n) - f_n(1 - f_m)) \\ &= \frac{1}{i\hbar} \sum_{m,n} f_m \langle m | [J^{(1)}(\delta\gamma), Q^{(1)}(\varphi)] | m \rangle. \end{aligned} \quad (56)$$

In the momentum space, the 0-chain $\varphi_p(\mathbf{q}) = V(\mathbf{q}) e^{\frac{i}{\hbar} q_\varphi \hat{n}_\varphi \cdot \mathbf{r}}$ is prescribed to be $V(\mathbf{q}) = \frac{i\hbar}{q_\varphi}$ so that the response has no explicit dependence on the electrical field $\mathbf{E}(\mathbf{q}) = -\frac{i}{\hbar} q_\varphi V$. Thus the Fourier transformation of (58) reads

$$\frac{1}{i\hbar} \langle [J(\delta\gamma), Q(\varphi)] \rangle_0 = \frac{1}{i\hbar} \sum_{m,n} f_m \left\langle m \left| \left[J_\gamma^{(1)}(\mathbf{q}), \frac{i\hbar}{q_\varphi} Q^{(1)}(-\mathbf{q}) \right] \right| n \right\rangle. \quad (57)$$

Inserting the first-quantized charge density operator

$$Q^{(1)}(\mathbf{q}) = e^{\frac{i}{\hbar} \mathbf{q} \cdot \hat{\mathbf{r}}} \quad (58)$$

and (33), the commutator in (59) is

$$[J_\gamma^{(1)}(\mathbf{q}), Q^{(1)}(-\mathbf{q})] = \frac{q^2}{2m} \left[(\hat{p}_\gamma + e^{-i\mathbf{q} \cdot \hat{\mathbf{r}}} \hat{p}_\gamma e^{i\mathbf{q} \cdot \hat{\mathbf{r}}}) - (\hat{p}_\gamma + e^{i\mathbf{q} \cdot \hat{\mathbf{r}}} \hat{p}_\gamma e^{-i\mathbf{q} \cdot \hat{\mathbf{r}}}) \right] = \frac{\hbar q^2 \cdot q_\alpha}{m} \delta_{\alpha\gamma}, \quad (59)$$

and thus

$$\frac{1}{i\hbar} \langle [J(\delta\gamma), Q(\varphi)] \rangle_0 = \frac{nq^2}{m} \delta_{\gamma\varphi}. \quad (60)$$

matches perfectly with the diamagnetic part.

2. Approach 2

The second approach is to change the integration variable in (48) and choose the contour as in FIG. 1 (by assuming the analyticity of the Kubo canonical pair).

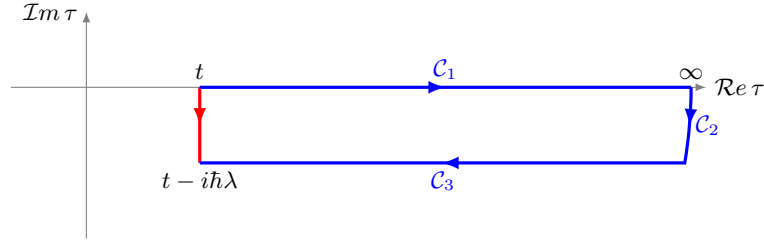

FIG. 1: **Complex- τ Plane.** Cauchy's theorem ensures that the integration along red path can be replaced by the integration along the blue path $C_1 + C_2 + C_3$, with the contribution over C_2 being vanishing.

Including the non-vanishing contribution from the contour C_1 and C_2 , we have, the conductivity tensor,

$$\begin{aligned} \sigma_{\gamma\varphi}(\omega) &= \lim_{s \rightarrow 0^+} \int_0^\infty dt e^{i\varpi t} \int_0^\beta d\lambda \langle J(\delta\gamma, t - i\hbar\lambda) J(\delta\varphi) \rangle = \frac{-1}{i\hbar} \lim_{s \rightarrow 0^+} \int_0^\infty dt e^{i\varpi t} \int_t^{t-i\hbar\beta} d\tau \langle J(\delta\gamma, \tau) J(\delta\varphi) \rangle \\ &= \frac{-1}{i\hbar} \lim_{s \rightarrow 0^+} \int_0^\infty dt e^{i\varpi t} \int_t^\infty dt' \left(\langle J(\delta\gamma, t') J(\delta\varphi) \rangle - \langle J(\delta\gamma, t - i\hbar\beta) J(\delta\varphi) \rangle \right) \\ &= \frac{-1}{i\hbar} \lim_{s \rightarrow 0^+} \int_0^\infty dt e^{i\varpi t} \int_t^\infty dt' \text{Tr} \left\{ \rho_0 \left(J(\delta\gamma, t') J(\delta\varphi) - e^{\beta H_0} J(\delta\gamma, t) e^{-\beta H_0} J(\delta\varphi) \right) \right\} \\ &= \frac{-1}{i\hbar} \lim_{s \rightarrow 0^+} \int_0^\infty dt e^{i\varpi t} \int_t^\infty dt' \text{Tr} \left\{ \rho_0 \left(J(\delta\gamma, t') J(\delta\varphi) - J(\delta\varphi) J(\delta\gamma, t) \right) \right\} \\ &= \frac{-1}{i\hbar} \lim_{s \rightarrow 0^+} \int_0^\infty dt e^{i\varpi t} \int_t^\infty dt' \langle [J(\delta\gamma, t'), J(\delta\varphi)] \rangle. \end{aligned} \quad (61)$$

Integration by parts, we get

$$\begin{aligned} \sigma_{\gamma\varphi}(\omega) &= \lim_{s \rightarrow 0^+} \frac{1}{\hbar\varpi} \left\{ e^{i\varpi t} \int_t^\infty dt' \langle [J(\delta\gamma, t'), J(\delta\varphi)] \rangle \Big|_0^\infty - \int_0^\infty dt e^{i\varpi t} \frac{d}{dt} \int_t^\infty dt' \langle [J(\delta\gamma, t'), J(\delta\varphi)] \rangle \right\} \\ &= \lim_{s \rightarrow 0^+} \frac{-1}{i\varpi} \left\{ \frac{-1}{i\hbar} \int_0^\infty dt \langle [J(\delta\gamma, t), J(\delta\varphi)] \rangle + \frac{1}{i\hbar} \int_0^\infty dt e^{i\varpi t} \langle [J(\delta\gamma, t), J(\delta\varphi)] \rangle \right\} \\ &\equiv \lim_{s \rightarrow 0^+} \frac{-1}{i\varpi} \left\{ \Sigma_{\gamma\varphi}(\omega) - \Sigma_{\gamma\varphi}(0) \right\} \end{aligned} \quad (62)$$

with the familiar response function $\Sigma_{\gamma\varphi}(\omega)$ for the *total* current.

Again if we try to go back to the system with quadratic dispersion relation up to linear response, we have to prove that $-\chi_{\gamma\varphi}(0)$ is indeed the diamagnetic part of contribution. In fact, by taking similar steps as (31) and working in momentum space, we get

$$-\Sigma_{\gamma\varphi}(\mathbf{q}, 0) = \dots = -\frac{1}{V} \sum_{m,n} (f_m - f_n) \frac{\langle m | J_{\gamma}^{(1)}(\mathbf{q}) | n \rangle \langle n | J_{\varphi}^{(1)}(-\mathbf{q}) | m \rangle}{\varepsilon_m - \varepsilon_n}. \quad (63)$$

And f-sum rule immediately tells

$$-\Sigma_{\gamma\varphi}(\mathbf{q}, 0) = \frac{nq^2}{m} \delta_{\gamma\varphi}, \quad (64)$$

matching perfectly with the diamagnetic part.

D. Matsubara Green Function of Imaginary-frequencies

Since the response function $\Sigma_{\gamma\varphi}(\omega)$ (or paramagnetic response function $\chi_{\gamma\varphi}(\omega)$) contains a kernel of retarded Green function $G_{J_{\gamma}J_{\varphi}}^R(\omega)$, we can also evaluate it with the help of Matsubara Green function (of current operators) on imaginary-frequency domain

$$\mathcal{G}_{J_{\gamma}J_{\varphi}}(i\omega_n) \equiv \int_0^{\beta} d\tau e^{i\omega_n\tau} \mathcal{G}_{J_{\gamma}J_{\varphi}}(\tau) \equiv \int_0^{\beta} d\tau e^{i\omega_n\tau} (-1) \langle \mathcal{T}_{\tau} J(\delta\gamma, \tau) J(\delta\varphi) \rangle = - \int_0^{\beta} d\tau e^{i\omega_n\tau} \langle J(\delta\gamma, \tau) J(\delta\varphi) \rangle.$$

and analytical continuation

$$G_{J_{\gamma}J_{\varphi}}^R(\omega) = \mathcal{G}_{J_{\gamma}J_{\varphi}}(i\omega_n) \big|_{i\omega_n \rightarrow i\omega + 0^+}.$$

The imaginary-time order is removed here just because the integration is performed on $[0, \beta)$ (essentially this comes from the (anti-)periodicity of the Matsubara Green function for boson (fermion) $\mathcal{G}(\tau) \equiv \mp \mathcal{G}(\tau + i\hbar\beta)$). This approach is gauranteed by the Lehmann spectral representation of their definition [4, 9]. For instance, Scalapino *et al.* [10] employ such method to study the fast and slow limits for metals, insulators, and superconductors.

III. APPENDIX

A. f-sum Rule

In this section, we will give a proof of the identity (36) used in the main text. Let me quote it here again **Theorem 1. (f-sum Rule)**

$$\sum_{m,n} (f_m - f_n) \frac{\langle m | J_{\alpha}^{(1)}(\mathbf{q}) | n \rangle \langle n | J_{\beta}^{(1)}(-\mathbf{q}) | m \rangle}{\varepsilon_{mn}} = -\frac{Nq^2}{m} \delta_{\alpha\beta}. \quad (65)$$

▷ Relabelling the states, we have, equivalently

$$\begin{aligned} \text{LHS} &= \sum_{m,n} f_m \frac{\langle m | J_{\alpha}^{(1)}(\mathbf{q}) | n \rangle \langle n | J_{\beta}^{(1)}(-\mathbf{q}) | m \rangle + \langle m | J_{\beta}^{(1)}(-\mathbf{q}) | n \rangle \langle n | J_{\alpha}^{(1)}(\mathbf{q}) | m \rangle}{\varepsilon_m - \varepsilon_n} \\ &= \sum_{m,n} f_m \frac{\frac{-1}{\hbar q^{\alpha}} (\varepsilon_m - \varepsilon_n)}{\varepsilon_m - \varepsilon_n} \left(\langle m | Q^{(1)}(\mathbf{q}) | n \rangle \langle n | J_{\beta}^{(1)}(-\mathbf{q}) | m \rangle - \langle m | J_{\beta}^{(1)}(-\mathbf{q}) | n \rangle \langle n | Q^{(1)}(\mathbf{q}) | m \rangle \right) \\ &= \frac{-1}{\hbar q^{\alpha}} \sum_m f_m \langle m | [Q(\mathbf{q}), J_{\beta}^{(1)}(-\mathbf{q})] | m \rangle, \end{aligned} \quad (66)$$

where in the second line, we make use of the momentum space charge conservation law

$$\frac{dQ(\mathbf{q}, t)}{dt} \equiv \frac{1}{i\hbar} [Q(\mathbf{q}), h] = -\frac{i}{\hbar} \mathbf{q} \cdot \mathbf{J}(\mathbf{q})$$

and take the quantum average over states $\langle m|$ and $|n\rangle$

$$(\varepsilon_n - \varepsilon_m) \langle m|Q(\mathbf{q})|n\rangle = q^\alpha \langle m|J_\alpha(\mathbf{q})|n\rangle \quad (67)$$

to replace the average of current operators. The commutator in (66) can be calculated by inserting the first quantized charge currents and charge densities (do not get confused with the charge q and momentum q_α ...)

$$[Q(\mathbf{q}), J_\beta(-\mathbf{q})] = \left[qe^{-\frac{i}{\hbar}\mathbf{q}\cdot\hat{\mathbf{r}}}, \frac{q}{2m}(\hat{p}_\beta e^{\frac{i}{\hbar}\mathbf{q}\cdot\hat{\mathbf{r}}} + e^{\frac{i}{\hbar}\mathbf{q}\cdot\hat{\mathbf{r}}}\hat{p}_\beta) \right] = \frac{q^2}{2m} \left[(e^{-\frac{i}{\hbar}\mathbf{q}\cdot\hat{\mathbf{r}}}\hat{p}_\beta e^{\frac{i}{\hbar}\mathbf{q}\cdot\hat{\mathbf{r}}} + \hat{p}_\beta) - (\hat{p}_\beta + e^{\frac{i}{\hbar}\mathbf{q}\cdot\hat{\mathbf{r}}}\hat{p}_\beta e^{-\frac{i}{\hbar}\mathbf{q}\cdot\hat{\mathbf{r}}}) \right] = \frac{q^2 \cdot q_\alpha}{m} \delta_{\alpha\beta}. \quad (68)$$

Thus we have

$$\text{LHS} = -\frac{q^2}{m} \delta_{\alpha\beta} \sum_m f_m = -\frac{Nq^2}{m} \delta_{\alpha\beta} = \text{RHS}.$$

□

Approach 1 can also be used to derive the integration form of f-sum rule:

Corollary 1. (Integration Form of f-sum Rule)

$$\frac{1}{2\pi} \int_{-\infty}^{\infty} d\omega \sigma_{\gamma\varphi}(\omega) = \frac{nq^2}{2m} \delta_{\gamma\varphi} \quad (69)$$

▷ Taking the form of conductivity tensor as (52) and change the order of integration, we have

$$\begin{aligned} \text{LHS} &= \lim_{s \rightarrow 0^+} \frac{1}{2\pi} \int d\omega \frac{1}{i\hbar} \int_0^\infty dt \langle [J(\delta\gamma, t), Q(\varphi)] \rangle_0 e^{i\omega t} = \frac{1}{i\hbar} \int_{-\infty}^{\infty} dt \theta(t) \langle [J(\delta\gamma, t), Q(\varphi)] \rangle_0 \delta(t) \\ &= \frac{1}{2i\hbar} \langle [J(\delta\gamma), Q(\varphi)] \rangle_0 = \frac{nq^2}{2m} \delta_{\gamma\varphi}, \end{aligned}$$

where in first line we take the Heaviside theta function $\theta(0) = \frac{1}{2}$ and in the second line we insert the equivalence with the diamagnetic part (60). □
